

Real fan data. Honest uncertainty.

We obtained 14 manufacturer data points. They differ from the brochure, so both calculations stay visible. Filters, guard losses and installed airflow are still unmeasured.

*Each parallel filter path is assumed to lose 5, 10 or 20 Pa at 400 m3/h total (200 through each filter). All R01 guard, plenum and installation allowances are retained.

Do not replace the old claim with a bigger number. OEM endpoint differences and supplied revision remain unresolved. Neither curve predicts CADR, HEPA performance or an outdoor bubble.

What filter can this assembly tolerate?

This table turns the airflow model into a useful component-screening requirement. The pressure remaining for each filter is the fan pressure minus all modeled non-filter losses.

Total m3/h	Each filter m3/h	Other losses / Pa	Filter Pa: brochure	Filter Pa: numeric
250.0	125.0	9.0	21.9	21.1
300.0	150.0	12.9	14.5	14.7
350.0	175.0	17.6	6.2	7.7
400.0	200.0	22.9	-3.2	-0.1

Decision: compare candidate filters at 150 and 175 m3/h per element. At 300 m3/h total, about 14.5 Pa remains for the filter. At 400 total, the assumed non-filter losses already exceed both fan curves. These balance limits are not validated safety margins.

Candidate, not selected: Camfil AQ13 407051002 is an OEM-listed nominal 20x20x2 inch filter. The current sheet does not establish the actual frame dimensions or low-flow resistance needed here. India contact route found; exact local stock, price and delivery UNKNOWN.

Existing S&P 990303 remains a dimensional reference only. Before cutting seats, confirm an obtainable filter, actual frame/seal dimensions and its clean/loading pressure curve. Mechanical, guards, electrical restart protection and physical commissioning remain unreleased.
